## Full analysis of ethylene tetramerisation product mixture

**Table 1.** Identified peaks of the light fraction of a standard ethylene tetramerisation sample as obtained using GC/MS.

Peak number	Identified peaks
1	Methyl propane
2	1-Butene
3	n-Butane
4	Acetone (syringe solvent)
5	1,5-Hexadiene
6	1-Hexene
7	n-Hexane
8	2-Hexene
9	Internal hexene
10	Methyl cyclopentane
11	Methylene cyclopentane
16	Methyl cyclohexane (reaction solvent)
18	1-Octene
19	4-Octene
20	Octane
21	2-Octene
22	2-Octene
23	Propenyl cyclopentane (3-cyclopentyl-1-propene)
25	Propyl cyclopentane

The numbered chromatogram that corresponds to Table 1 is shown in Figure 1.

**Figure 1.** Numbered chromatogram (see Table1) of light fraction of tetramerisation sample

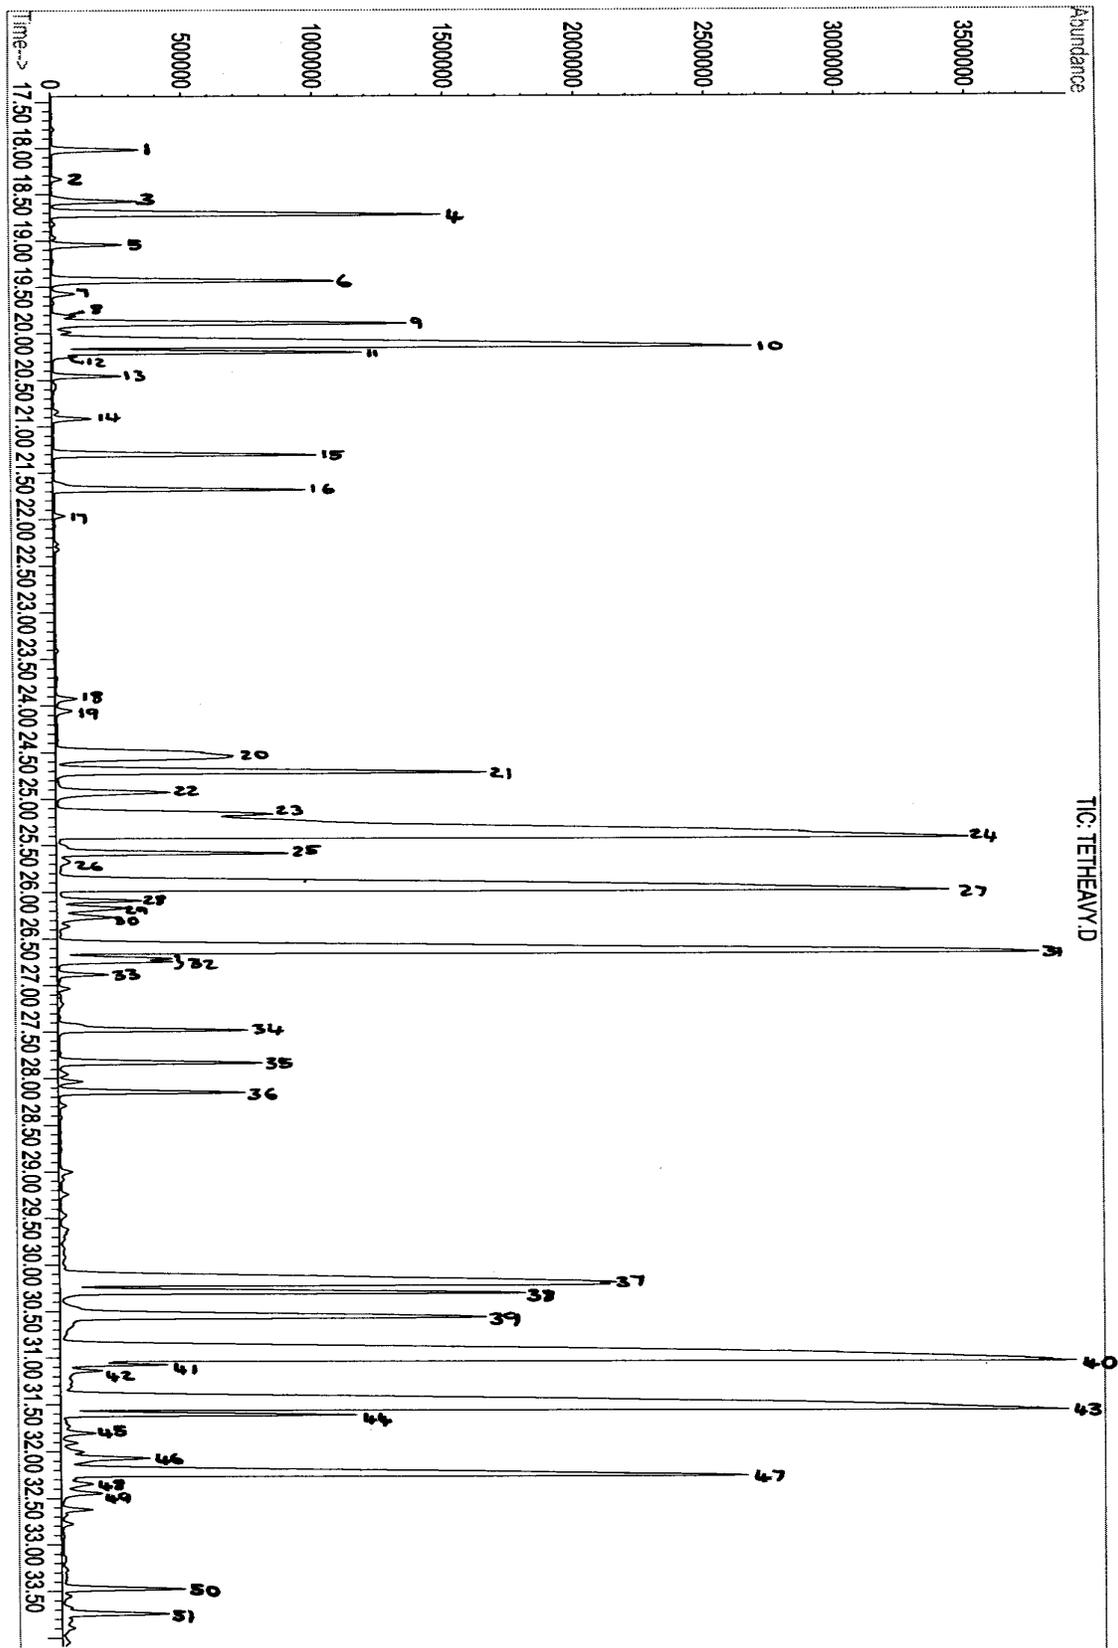

**Table 2.** Identified peaks of the heavy fraction of a standard tetramerisation sample as obtained using GC/MS (Identified secondary products in bold)

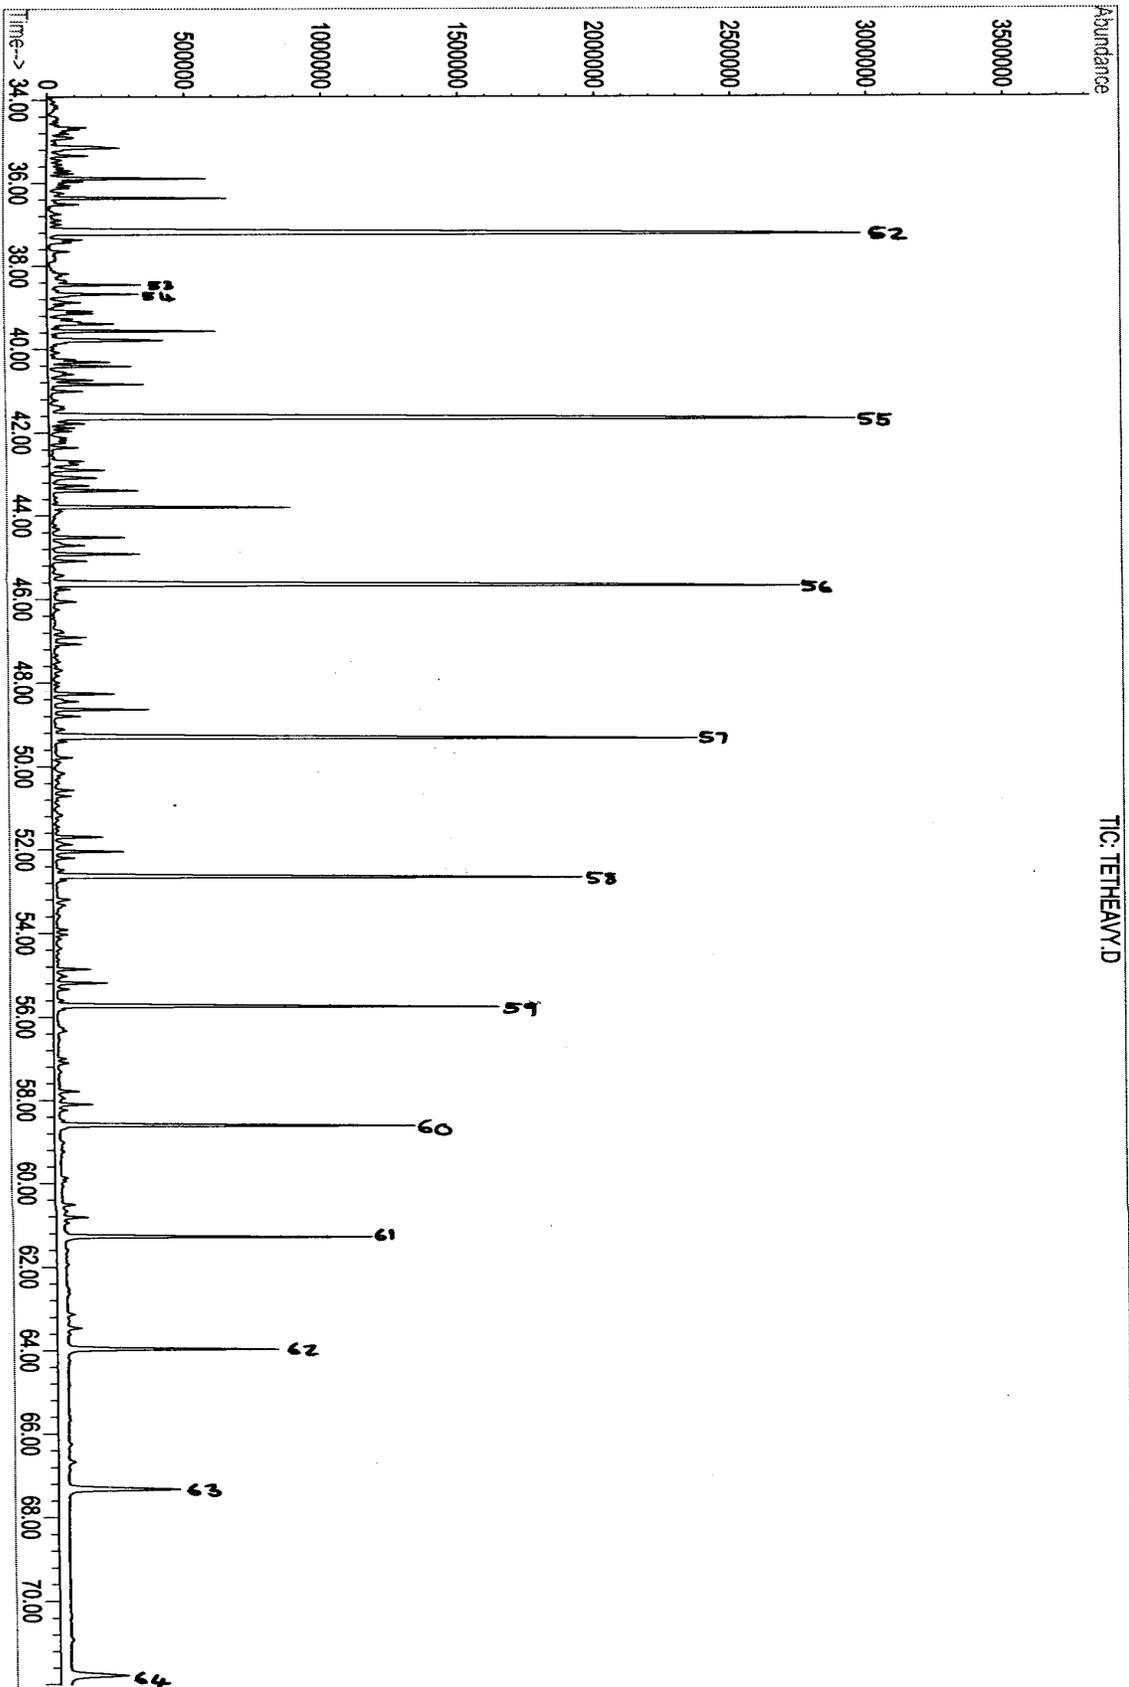

Peak number	Identified Peaks
3	<b>(4-Ethyl-1-octene)</b>
4	<b>(5-Methyl-1-nonene)</b>
6	<b>5-Methylene nonane</b>
9	<b>(3-Propyl-1-heptene)</b>
10	1-Decene
11	<b>Internal decene</b>
12	<b>Internal decene</b>
13	n-Decane
15	(Pentenyl cyclopentane)
16	Pentyl cyclopentane
24	<b>(5-Methyl-1-undecene)</b>
27	<b>5-Methylene undecane</b>
31	1-Dodecene (c.a. 40%) + co-eluent
33	Dodecane
35	Heptenyl cyclopentane
36	Heptyl cyclopentane
40	<b>(7-Methyl-1-tridecene)</b>
43	<b>7-Methylene tridecane</b>
47	1-Tetradecene
49	Tetradecane
50	(Nonenyl cyclopentane)
51	(Nonyl cyclopentane)
52	1-Hexadecene
53	(Undecenyl cyclopentane)
54	(Undecyl cyclopentane)
55	1-Octadecene
56	C20 1-alkene
57	C22 1-alkene
58	C24 1-alkene
59	C26 1-alkene
60	C28 1-alkene

Products in brackets were not unambiguously identified but may be deduced with a high degree of probability from first principles and comparative mass spectra of related compounds in the Wiley275 library.

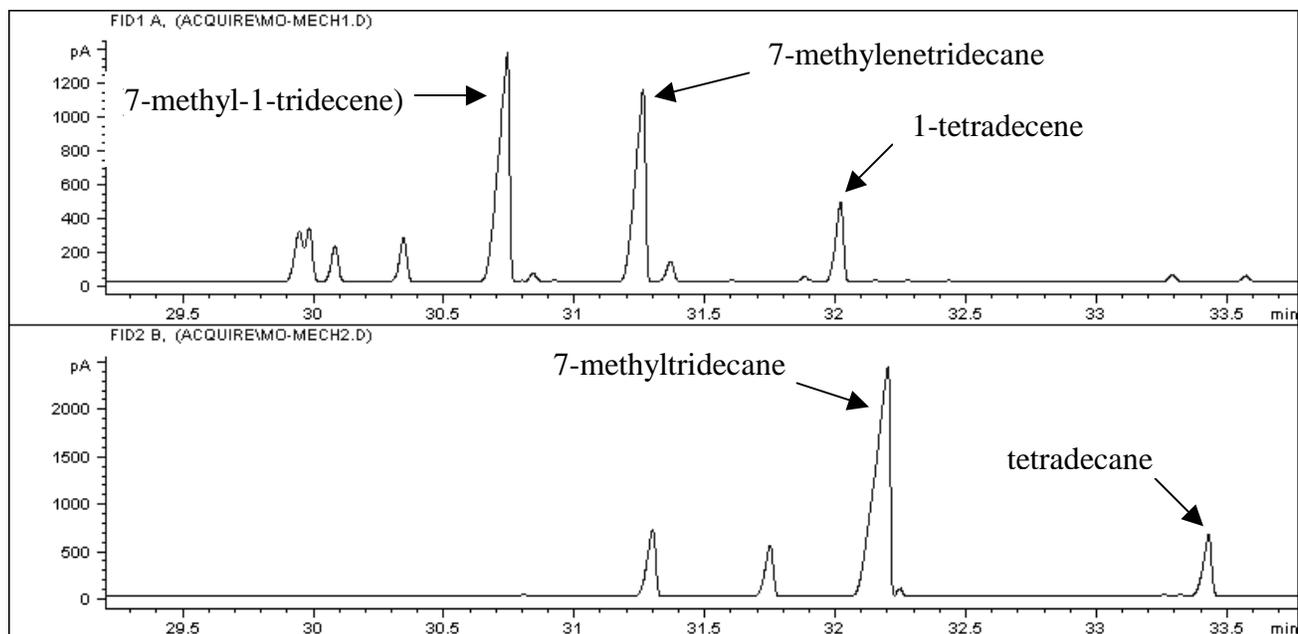

The numbered chromatogram that corresponds to Table 2 is shown in Figure 2.

Figure 2. Numbered chromatogram (see Table2) of heavy fraction of tetramerisation sample

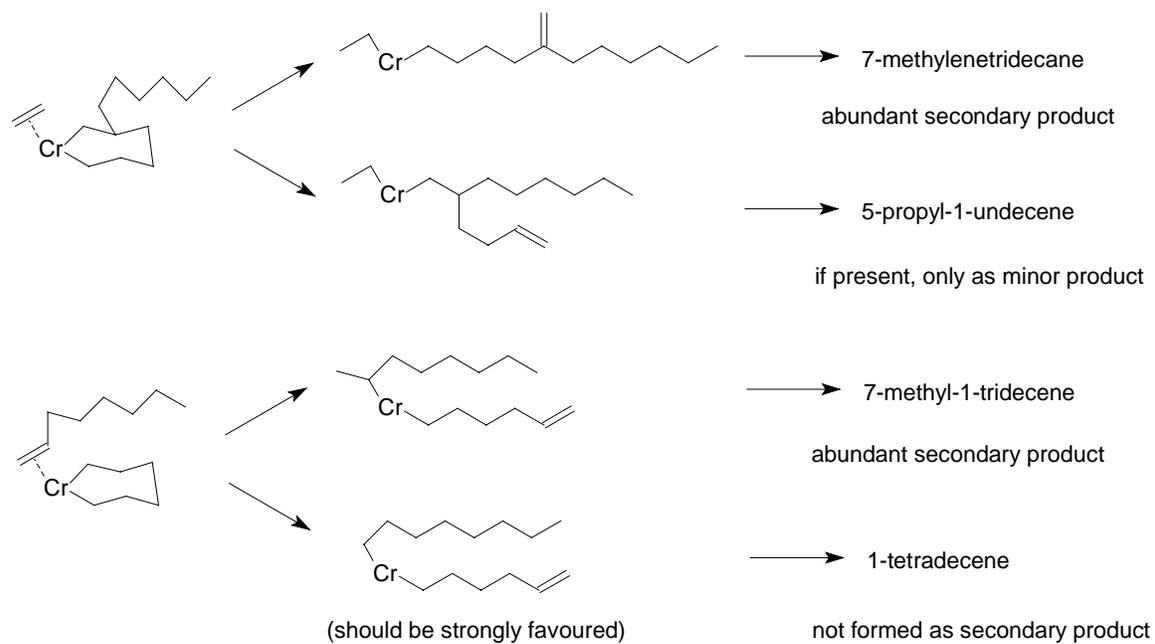

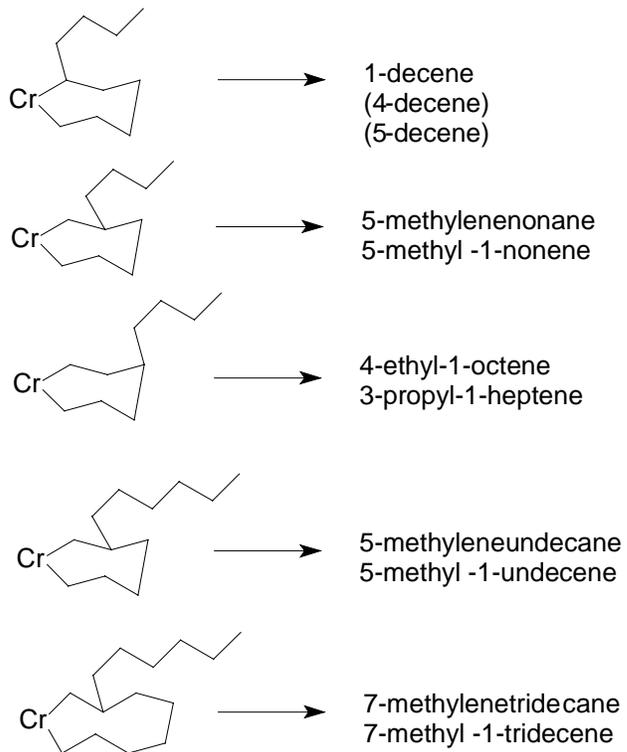

**Figure 3.** GC-FID chromatogram of the C14 region: unhydrogenated and hydrogenated (no correspondence of elution times as different columns were used)

**Figure 4.** Postulated origin of 7-methylenetridecane and 7-methyl-1-tridecene *via* alternative tetramerisation mechanism ( $\beta$ -hydride transfer to alkene) and other secondary products expected in this case

**Figure 5.** Metallacyclic origin of secondary products that could be identified

## Mathematical analysis for deuterium labeling studies

### Metallacyclic:

If the ratio of  $C_2H_4:C_2D_4$  is defined as  $x$  ( $x$  may easily be calculated from the observed isotopomer distribution; this is independent of mechanism), then the isotopomer distribution will follow the generalized Pascal's triangle distribution:

	<b>C<sub>2</sub>H<sub>4</sub></b>		<b>C<sub>2</sub>D<sub>4</sub></b>									
<b>C2</b>	$x$		1									
	<b>C<sub>4</sub>H<sub>8</sub></b>		<b>C<sub>4</sub>H<sub>4</sub>D<sub>4</sub></b>		<b>C<sub>4</sub>D<sub>8</sub></b>							
<b>C4</b>	$x^2$		2x		1							
	<b>C<sub>6</sub>H<sub>12</sub></b>		<b>C<sub>6</sub>H<sub>8</sub>D<sub>4</sub></b>		<b>C<sub>6</sub>H<sub>4</sub>D<sub>8</sub></b>		<b>C<sub>6</sub>D<sub>12</sub></b>					
<b>C6</b>	$x^3$		$3x^2$		3x		1					
	<b>C<sub>8</sub>H<sub>16</sub></b>		<b>C<sub>8</sub>H<sub>12</sub>D<sub>4</sub></b>		<b>C<sub>8</sub>H<sub>8</sub>D<sub>8</sub></b>		<b>C<sub>8</sub>H<sub>8</sub>D<sub>12</sub></b>		<b>C<sub>8</sub>D<sub>16</sub></b>			
<b>C8</b>	$x^4$		$4x^3$		$6x^2$		4x		1			
	<b>C<sub>10</sub>H<sub>20</sub></b>		<b>C<sub>10</sub>H<sub>16</sub>D<sub>4</sub></b>		<b>C<sub>10</sub>H<sub>12</sub>D<sub>8</sub></b>		<b>C<sub>10</sub>H<sub>8</sub>D<sub>12</sub></b>		<b>C<sub>10</sub>H<sub>4</sub>D<sub>16</sub></b>		<b>C<sub>10</sub>D<sub>20</sub></b>	
<b>C10</b>	$x^5$		$5x^4$		$10x^3$		$10x^2$		5x		1	

It is possible to calculate a first order correction for the natural abundance of deuterium in normal ethylene (0.79%) and the residual abundance of hydrogen in the deuterated ethylene (0.5% from manufacturer's analysis). This correction is demonstrated for 1-hexene below.

Isotopomer	Idealised metallacyclic mechanism	Correction for imperfect C <sub>2</sub> H <sub>4</sub> and C <sub>2</sub> D <sub>4</sub>
C <sub>6</sub> H <sub>12</sub>	x <sup>3</sup>	x <sup>3</sup> (1-0.0079*12)
C <sub>6</sub> H <sub>11</sub> D <sub>1</sub>		x <sup>3</sup> (0.0079*12)
C <sub>6</sub> H <sub>10</sub> D <sub>2</sub>		0
C <sub>6</sub> H <sub>9</sub> D <sub>3</sub>		3x <sup>2</sup> (0.005*4)
C <sub>6</sub> H <sub>8</sub> D <sub>4</sub>	3x <sup>2</sup>	3x <sup>2</sup> (1 – 0.005*4 – 0.0079*8)
C <sub>6</sub> H <sub>7</sub> D <sub>5</sub>		3x <sup>2</sup> (0.0079*8)
C <sub>6</sub> H <sub>6</sub> D <sub>6</sub>		0
C <sub>6</sub> H <sub>5</sub> D <sub>7</sub>		3x(0.005*8)
C <sub>6</sub> H <sub>4</sub> D <sub>8</sub>	3x	3x(1 – 0.005*8 – 0.0079*4)
C <sub>6</sub> H <sub>3</sub> D <sub>9</sub>		3x(0.0079*4)
C <sub>6</sub> H <sub>2</sub> D <sub>10</sub>		0
C <sub>6</sub> H <sub>1</sub> D <sub>11</sub>		1(0.005*12)
C <sub>6</sub> D <sub>12</sub>	1	1(1-0.005*12)

### Cossee mechanism:

In the Cossee linear chain growth mechanism, H/D scrambling occurs, and isotopomers with odd numbers of H or D are predicted. The isotopomers are of the form (C<sub>2</sub>H<sub>4</sub>)<sub>m</sub>(C<sub>2</sub>D<sub>4</sub>)<sub>m</sub> – (H or D) + (H or D).

The following assumptions or approximations are made:

- 1) The probability of H v/s D lost ( $\beta$ -H/D elimination) is determined by the H:D ratio in the isotopomer
- 2) The probability of the H v/s D gained (insertion into Cr-H/D) is determined by the value of x (the ratio of C<sub>2</sub>H<sub>4</sub>:C<sub>2</sub>D<sub>4</sub>)
- 3) Kinetic isotope effects may be discounted

As an example, the calculation of relative amounts for 1-hexene is shown below:

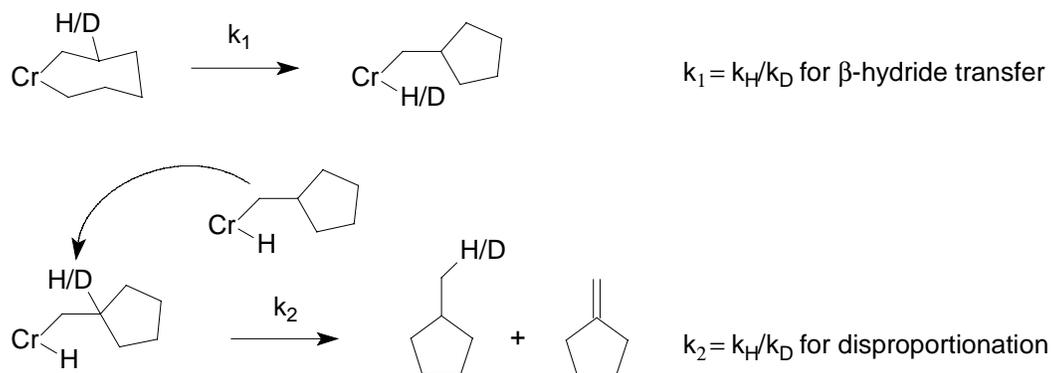

$(C_2H_4)_m(C_2D_4)_n$		$(C_2H_4)_m(C_2D_4)_n$ - (H or D) (Red: loss of H Blue: loss of D)		$(C_2H_4)_m(C_2D_4)_n$ - (H or D) + (H or D) (Red: gain of H Blue: gain of D)	
$C_6H_{12}$	$x^3$	$C_6H_{11}$	$x^3$	$C_6H_{12}$	$x^4$
				$C_6H_{11}D_1$	$x^3$
				$C_6H_{10}D_2$	
				$C_6H_9D_3$	$x^3$
$C_6H_8D_4$	$3x^2$	$C_6H_8D_3$ $C_6H_7D_4$	$x^2$ $2x^2$	$C_6H_8D_4$	$x^2 + 2x^3$
				$C_6H_7D_5$	$2x^2$
				$C_6H_6D_6$	
				$C_6H_5D_7$	$2x^2$
$C_6H_4D_8$	$3x$	$C_6H_4D_7$ $C_6H_3D_8$	$2x$ $x$	$C_6H_4D_8$	$2x + x^2$
				$C_6H_3D_9$	$x$
				$C_6H_2D_{10}$	
$C_6D_{12}$	1	$C_6D_{11}$	1	$C_6H_1D_{11}$	$x$
				$C_6D_{12}$	1

The distribution can now be corrected for the natural abundance of deuterium in the normal ethylene and the imperfectly labeled deuterated ethylene. The first order correction is made as for the metallacyclic mechanism.

### Disproportionation mechanism for the formation of C6 cyclics:

The prediction of an isotopomer distribution must take account of two different kinetic isotope effects in operation (Scheme 1), relating to: i)  $\beta$ -H/D elimination to the metal from the metallacycloheptane ( $k_1$ ), and ii) H/D transfer in the disproportionation step ( $k_2$ )

**Scheme 1.** Kinetic isotope effects for the disproportionation mechanism of cyclic formation

The following assumptions/approximations are made:

- 1) For a given metallacycloheptane isotopomer, the normal and deuterated ethylenes are statistically distributed in the metallacycle (no secondary isotope effects)
- 2) The ratio of  $\beta$ -H :  $\beta$ -D elimination from a given metallacycloheptane isotopomer =  $k_1 * (\text{number of H's in isotopomer}) : (\text{number of D's in isotopomer})$
- 3) All steps are irreversible

The calculation of relative amounts is shown below:

Metalla-cyclopentane	Corrected for imperfect C <sub>2</sub> H <sub>4</sub> and C <sub>2</sub> D <sub>4</sub>	After β-H/β-D transfer	red: loss of β-H; blue: loss of β-D	Methyl-cyclopentane	(*) red: gain of H; blue: gain of D

MC <sub>6</sub> D <sub>12</sub>	$1(1-0.005*12)$	= j	<b>ik<sub>1</sub>/(11+k<sub>1</sub>) + j</b>	C <sub>6</sub> D <sub>12</sub>	<b>L</b>

(\*) **Z = ratio of H v/s D transfer for the disproportionation step.** This is dependent on the **ratio of H v/s D available (Y)** and on the **intrinsic kinetic isotope effect (k<sub>2</sub>)** for the disproportionation. Y and Z may be calculated as follows:

### Calculation of Y:

Y = ratio of H : D available for disproportionation transfer = ratio of  $\beta$ -H :  $\beta$ -D transfer from metallacycloheptane

(The cyclisation is such that the H or D available for disproportionation transfer comes from the same ethylene as the H or D lost in the  $\beta$ -hydride transfer.) Thus,

$$Y = [a + 11bk_1/(1+11k_1) + 9ck_1/(3+9k_1) + 8dk_1/(4+8k_1) + 7ek_1/(5+7k_1) + 5fk_1/(7+5k_1) + 4gk_1/(8+4k_1) + 3hk_1/(9+3k_1) + ik_1/(11+k_1)]$$

---

$$[b/(1+11k_1) + 3c/(3+9k_1) + 4d/(4+8k_1) + 5e/(5+7k_1) + 7f/(7+5k_1) + 8g/(8+4k_1) + 9h/(9+3k_1) + 11i/(11+k_1) + j]$$

### Calculation of Z:

Cyclopentylmethyl moieties either have H or D available for disproportionation transfer, ratio H:D = Y.

For disproportionation, there are three possible combinations of these moieties:

Combinations	Relative probability of this combination	Probability of transfer	H	Probability of transfer	D
(H, H)	$Y^2$	$Y^2$		0	
(H, D)	$2Y$	$2Yk_2/(1+k_2)$		$2Y/(1+k_2)$	
(D, D)	1	0		1	

Thus,

$$Z = \frac{Y^2 + 2Yk_2/(1+k_2)}{2Y/(1+k_2) + 1}$$

**Isotopomer distributions generated with these calculations (scaled such that peaks of maximum intensity are equal) relative to the observed isotopomer distributions (determined by using the integrated molecular ions extracted from the GC-MS total ion chromatogram)**
